Communicated to the Virginia State Agricultural

REVIEW

Of "An Essay on Calcareous Manures by Ed. Ruffin, fifth eartion, amended and enlarged:" J. W. Randolph, Richmond, 1853.

BY HON. WILLOUGHBY NEWTON.

[Published by order of the Executive Committee.]

The farmers of Virginia have just reason to thank both the author and publisher for this enlarged and improved edition of a most valnable book. A recent biographical sketch of the author, as graceful as it is just, has presented us with some of the incidents of his early life. From these we learn how few adventitions advantages he had for the performance of the difficult task which he has so well executed. At a very early age, with habits of study unformed, we find him leaving the walls of the college for the camp. After a very brief service as a soldier, having just attained his nineteenth year, he entered upon his pa-ternal estate, which he found greatly impo-verished. With an ardent zeal that has never known abatement, he commenced, without knowledge, either theoretical or practical, the hopeless task of enriching it. He studied all the foreign authors on agriculture that came within his reach. He followed with untiring industry the instructions of "Arator," but all to little purpose. His labors, like those of Sysiphus, were never ending, and ever to be performed. He became convinced that some fatal error existed in our modes of culture and efforts at improvement, and he determined, if possible, to find it out. A remarkable talent for observation, and a sagacity almost intuitive, soon enabled him, without other aid, to find the true path, whilst Young and Sinclair and Peters and Taylor and others, almost equally distinguished for learning and agriequally distinguished for fearining and agricultural experience, were groping in the dark. In the month of October, 1818, he announced in a communication to the Agricultural Society of Prince George, for the first time, at least in this country, the cause of the general sterility of lands, and the proper remedy. This communication, though unpretending in

its character, and written before the author had any experience as a writer, is the germ of the "Essay." And whilst it states, with singular clearness, the points insisted on, is distinguished by a force of reasoning and a purity and vigor of style which could only have been acquired by a careful study of the great masters of the English language, whose works at that day graced the library of every Virginia gentleman, and had not then been superseded by the cheap literature which now threatens to sweep away all sound learning in its eternal wishy-washy flood.

The author in his preface alludes to this communication, an extract from which is published in the appendix to this edition of the Essay, and vindicates his claim to originality in the four following specifications of discovery which he was the first to announce:

"I. The capacity of impoverished soils for receiving improvement from putrescent maqures, being in proportion to their original or natural measure of fertility; and that soils naturally poor (especially in this country) could not be enriched by these manures, durably or profitably, above their natural degree of productiveness.

of productiveness.

"2. The almost universal and total absence of carbonate of lime in the soils of the Antlantic slope of Virginia, and (by inference) of most others of the United States—and even in most limestone soils—while, from all existing testimony of preceding writers on agriculture, the very general, if not universal prevalence of carbonate of lime would have been inferred by every reader.

by every reader.

"3. The general presence of some vegetable acid in all our naturally poor soils, and this acid acting as a cause of sterility.

"4. The application of carbonate of lime to soils deficient in that necessary element, serving to neutralize the acid—and, by that and other stated and important operations or effects, serving to fit the before poor and unimprovable soils for speedy and profitable improvement."

It is unquestionable that our author was the first, at least in this country, to make the distinct announcement of these important truths. And his credit is not the less, even as an original discoverer, though it be admitted that the same opinions were contemporaneously expressed by eminent men in other countries, of whose views he was entirely ignorant. Such,

Vol. XIII.-5.

indeed, is the usual progress of scientific discovery. It rarely happens that to any one man is due the entire credit of first conceiving and successfully carrying forward a great improvement. Doubtless, many philosophers at the time of Franklin's great discovery were speculating on the nature of electricity, the practical illustration of which has rendered his name immortal. Yet of no other person is it said, eripuit fulmen calo sceptrumque tyrannis.

The claim for original discovery, as set forth in the first two specifications, is distinctly recognised by one of the highest agricultural authorities of Great Britain. J. C. Loudon, the Editor of the "Gardener's Magazine," in the year 1836, used the following language: 'Mr. Ruffin has the merit of first pointing out that there can be no such thing as a naturally fertile soil without the presence of calcareous earth; but where this earth is present, the soil, however exhausted it may have been by culture, will, when left to itself, after a time regain its original fertility; that soils which contain no calcareous earth are never found naturally fertile; and that all that art can do to them, exclusive of adding calcareous earth, is to force crops by putrescent manures; but that when these manures are withheld the soil will speedily revert to its original sterility." And so important did he deem this announcement, that at the close of the year he again alludes to it in the following manner: "In agricultural science the only point that we can re-collect worthy of notice, that has occurred during the past year, is the advancement of the principle by the American agricultural writer, Mr. Ruffin, that no soil whatever will continue fertile for any length of time that does not contain calcareous matter. This we believe was never distinctly stated as a principle, by Kirwan, Chaptal, Davy or any other European chemist or agriculturist." The application of lime and marl for the improve-ment of the soil has been very extensive in Europe for many centuries, even going back to the time of the ancient Romans, yet it cannot be denied that its use, even by the most scientific agriculturists, has, until very lately, been entirely empirical. The numerous authorities, collected with great research by our author, prove beyond question that the peculiar qualities of marls were not properly appreciated, and that various earths were used indifferently under the name of marl, without the least reference to the amount of calcareous matter contained in them. In confirmation of the opinions expressed and sustained by the numerous authorities cited, we will quote some expressions of Petzholdt from his lectures published in London as late as 1844; a writer certainly of great clearness and ability, though he is charged by his contemporaries with having propagated some gross errors: "Lime, in its calcined state termed quicklime, is undoubtedly most frequently used in agri-culture with the view to directly fertilizing the

only to a very slight extent, or in a few rare instances, since cultivated plants will find as much lime in the soil as they require for their growth and perfection, owing to the exceedingly profuse diffusion of lime upon the surface of the earth; so that an artificial supply of this substance would appear to be, in this respect, perfectly superfluous."

In regard to marl he says, "So much, however, is deducible from all experience, that the mere application of marl to an exhausted soil is of no use whatever, unless it is carried on the field in such quantities as to constitute a new soil, covering the whole surface to the depth of a foot!" Professor J. F. W. Johnston has given indubitable evidence in his lectures, also, first published in England in 1844, that he thoroughly understood the whole subject, and with the aid of his scientific knowledge has been very successful in its elucidation. Yet no careful and intelligent reader can doubt, from the internal evidence afforded by the two works, that the Essay on Calcareous Manures, furnished the great principles which the Professor has so successfully elaborated in his lectures on lime and marl. He does not give his views as at all new, or original, yet they had been stated before by no British writer. Of the existence and contents of the "Essay" he could not have been ignorant. Four editions had been published in this country. It was republished in the Farmers' Register, and extensively commented upon, and commended by the agricultural press throughout the United States, and, as we have already seen, noticed with the highest approbation by one of the first British agricultural authors, and also re-published almost literally in the British Farmer's Magazine. It was also reviewed in a most complimentary manner in Silliman's Journal, a work of high reputation and extensive circulation among men of science throughout the world, and which work we find quoted by the lecturer. To suppose that Professor Johnston was either ignorant of this work or that he did not avail himself of its facts and reasonings in preparing his lectures, would be to impute to him a degree of negligence and indolence, in striking contrast with the industry, research, and accurate knowledge of facts, affecting the interests of agriculture in all parts of the world, displayed in almost every page of his learned and valuable work.

The claim of our author to the discovery of acids in soils, and the first announcement of its injurious effects on agriculture, cannot, we fear, be so easily vindicated. For years after the publication of his views we supposed his claim to originality would never be contested. The fact of the existence of acids in soils was doubted by all, denied by many, and ridiculed as unphilosophical by those who affected to be particularly learned. We find, however, that Thaër, perhaps the most justly renowned of European scientific agriculturists, had either contemporaneously with him or in advance soil. It can, however, answer this purpose of our author, made a public announcement

of the same truths. On page 82 of the Essay | will be found a note containing the views of Thaer, with Mr. Ruffin's comments. The trnth of history constrains us to express it as our opinion that to Thaer is due the credit of having first presented to the public those important truths. The first edition of his great work was published in 1812. We have no evidence that any second edition was published during his life, which closed after near two years of illness, on the 26th of October, 1828. A chronological list of his writings accompanying his treatise on agriculture, published in the Farmer's Library, makes no mention of any publication by him later than 1815, except one on wool and sheep breeding, in 1825. It is certain, therefore, that the facts and reasonings in regard to acids in soils, must have been made public before 1833, the period fixed by our author as that subsequent to which he supposed these views were added in a new edition. We think, moreover, there is internal evidence that they were part of the original work. They are so perfectly incorporated with Tbaer's reasoning on humus that they could not be struck out without destroying the unity of the whole. As a mere matter of literary curiosity it would be very gratifying to see the first edition of Thaer's great work, if more than one edition was published by him, which would be conclusive of the question.

We have deemed these prefatory remarks due to the author of the book under review, whose labors have marked an era in the history of agriculture, and whose services to Virginia and to mankind cannot, in our estimation, be too highly appreciated. If the limits prescribed to us would permit we would gladly enter npon the examination of the entire work, and point out the many striking views of the author, in which we entirely concur. In this respect we must content on rselves with recommending it most cordially to the agricultural public, and especially to the young farmers of Virginia with the assurance that every intelligent and careful reader will find in it much instruction and abundant food for thought.

Premising that every reader of this review shall also read "the Essay" with proper attention, we think that our task will be much more satisfactorily performed, and the cause of trne knowledge better promoted by noticing in a spirit of just discrimination the few points on which we differ in opinion with the author, rather than the very many on which we en- Wakefield," to which we beg leave to retirely agree with him. We propose, there- the reader, for edification and amusement. fore, briefly but freely to discuss some important questions, as well of theory as of practice, considered in the Essay; and in the course of our observations we shall suggest for the adoption of the cultivators of poor lands a mode by which, taking the instructions of our author as the basis of their operations, they may improve their farms much more speedily, profitably and cheaply than by the use of calcareons manures, as usually applied. We

of our capacity for the undertaking. A learned professor has truly said "that the art of culture is almost entirely a chemical art, since nearly all its processes are to be explained only on chemical principles." How is the practical farmer, who has not entered a chemical laboratory for thirty years, to be suffi-cient for such a task? He must derive his instructions entirely from books and his own unaided observations in the field. Upon many important points of theory and practice some of the most enlightened authors are at issue. And unfortunately, whilst among them there are many true disciples who worship at the altar of science with proper docility and humility, always ready to confess the limits of human knowledge, there are others, on the contrary, mere empty pretenders, who either delude themselves with a vain show of knowledge, or seek to impose upon the understanding of the ignorant by unmeaning verbiage.

As an illustration of our remark we may mention that to aid us in our present investigations, we took up a late edition of Turner's Chemistry, said in the preface, to combine the learning of Turner, Liebig, Gregory and of two American professors. We turned to the process of fernientation for instruction, as to the chemical agencies at work in that operation of Nature, deemed so important by the practical farmer, and to our great edification we were informed: "Now, we can offer no other explanation of these facts of fermentation than this, that when a body in a state of progressive change, the particles of which are consequently in a state of motion, is placed in contact with another body, the particles of which are in a state of unstable equilibrium, the amount of motion mechanically communicated to the particles of the latter from those of the former, is sufficient to overturn the existing equilibrium, and by the formation of a new compound establish a new equilibrium, more stable under the given circumstances." We are gravely told "There is nothing unphilosophical in this explanation, and it is to be considered as the best theory of fermentation yet attempted." [Turner's Chemistry, Rogers, pp. 537-8.1

If this be philosophy, we beg to be informed what is nonsense. Our reading furnishes no better parallel for this profound disquisition than the very learned discourse of the re-nowned Mr. Jenkinson, in the "Vicar of Wakefield," to which we beg leave to refer

It would be well for the advancement of true learning, if professors, whose duty it is to teach the rising generation useful and practical knowledge, would imitate the clear and vigorous style of our author, whose reasonings though often profound, are always intel-

ligible.
Whilst it cannot be denied that in the department of agricultural chemistry much has already been accomplished, yet to the earnest enter upon this discussion with great diffidence inquirer after truth, it is obvious that much

more is yet to be done before its claims to the ! character of an exact science can be success-

fully asserted.

In its present condition, of doubt and uncertainty, the student of Nature, athirst for knowledge, enters with ardor on the pursuit, and traverses an arid waste, with only here and there a green spot to cheer him on his way, hoping, ere long, to refresh himself at the pure fountain of truth; but finds, at last, that he must be content with the muddy waters of a broken cistern. He cannot reconcile the conflicting opinions of the learned, nor comprehend their discordant facts. To him all is confusion, and he vainly attempts to educe order out of chaos, until weary with the effort, he exclaims, when will another Bacon arise, who with cautious step and comprehensive grasp, shall collect, arrange and classify our existing knowledge, distinguish clearly the bounds of the known and the unknown, and open anew the pathway of true investigation! Professor Johnson in his lectures, which we take pleasure in commending as replete with good sense and sound learning, has the following just remarks: "The history of science shows, by many examples, that those men who adopt extreme views—who at-tempt to explain all phenomena of a given kind, by reference to a single specific causehave ever been of very great use in the advancement of certain knowledge. Their arguments, whether well or ill founded, lead to discussion, to further investigation, to the discovery of exceptional cases, and finally to the general adoption of modified views which recognise the action of each special cause in certain special cases, but all in subordination to some more general principle.

"Thus, if some ascribe the fertility of the soil to the presence of the alkalies in great abundance, others to that of the phosphates, others to that of lime, others to that of alumina, and others, finally, to that of vegetable matter in a soluble state, all these extreme opinions are reconciled, and their partial truths recognised, in one general principle, that a soil to be fertile must contain all the substances which the plant we desire to grow can only obtain from the soil, and in such abundance as readily to supply all its wants; while at the same time it must contain nothing hurtful to vegetable life." (Page 288.)

In speaking of his early labors and of his earnest endeavors to impress his views upon others, our author very happily describes himself as "an enthusiastic and successful projector." Of his eminent success, the result of his labors in enriching himself and adding vastly to the resources of the Commonwealth, is conclusive evidence, whilst the ardor with which he is known to devote himself to any object which he deems useful or praiseworthy gives assurance that he has a full stock of that enthusiasm, without which nothing great was ever accomplished, and which indeed is the "open sesame" to success in all important | paratively a few farms, lying on the Pamunkey

ever, so indispensable to success in all active pursuits, is not the best suited for calm and impartial philosophical investigation. It is very apt to cause an entire concentration of the faculties upon the great end to be achieved, whilst other matters, perhaps equally impor-tant, not coming fully within the scope of the intellectual vision, like objects seen in the distance, lose their just proportions.

The Essay on Calcareous Manures, as its title

imports, is intended to illustrate the importance and necessity of one special means of improvement. To be scientifically accurate, and to prevent all misconception of his true object, the author has introduced a new term, "calxing," to distinguish the special operation recommended, from the more complex opera-

tion, usually termed marling.

Under this term he embraces lime, whether quick or effete, and the carbonate of lime, in every form in which it can be presented; whilst sulphate and phosphate of lime are excluded, though having the same base, and possibly in some of their transformations in the earth, the same effect, they might, with propriety, be embraced under the general head of calcareous manures. This exclusive idea has had a prominent place in all the former editions, and although in the present one, the author has very properly availed himself of the new lights afforded by agricultural chemistry to modify such of his views as seemed to him to require change, he has seen no reason to modify them at all in regard to the peculiar value of calxing.

He has, on the contrary, found in modern writers new views which have been used with great ingenuity and ability to enhance his estimate of the advantages of this peculiar operation. We are, if possible, more and more convinced by every day's experience and ob-servation, of the indispensable necessity of calking to the improvement of our naturally poor lands. It is indeed the fulcrum on which to fix the lever of improvement, and without it we are entirely powerless. Yet it is to be feared that unreflecting persons, influenced by the earnest reasonings of the Essay, and by the extraordinary success of Mr. Ruffin and his neighbors, may adopt erroneous opinions. Their great improvements, though mainly attributed to calxing, are, in a great measure, due to other most valuable enriching materials existing in the Pamunkey marl. And persons who attribute these remarkable effects to calxing alone, while themselves using a very different article, will certainly be disappointed in their expectations, and perhaps abandon in disgust all efforts at improvement. The marl used, with such striking effect, by Mr. Ruffin The marl and others, in the neighborhood of Newcastle, contains about 40 per cent. of carbonate of lime, and is what is known as eocene marl, and is confined, so far as yet ascertained, to a few limited localities. It has been applied on comenterprises. This constitution of mind, how- and James rivers. We learn, as we now write,

upon the best authority, that Professor Gilham | has found by recent analysis that it contains, besides carbonate of lime, a large per centage of sulphate of lime, and also, in particular samples, large proportions of ammonia and phosphoric acid. These marls are almost guano and calx combined, and their effect is not surprising, when this fact is understood. The miocene marls, on the contrary, are found absolutely destitute of these fertilizing ingredients, and owe their value entirely to carbon-ate of lime, and are the only marls known or accessible in much the larger portion of Eastern Virginia. We look with interest to the forthcoming report of Professor Gilham, in confirmation of our views.* Deeming this a subject of vast importance in the present stage of agricultural progress in Virginia, we shall present our views upon it somewhat at large in the following pages. The power of calxing has prescribed limits, beyond which it cannot We believe there has been no instance in Virginia, or elsewhere, nor do we think it possible that there can ever be one, of the product of any naturally poor farm being brought up to an average on entire fields, from year to year, of more than ten bushels of wheat and twenty bushels of merchantable corn, to the acre, by calking alone, however long continued, though the operation be aided by the use of all the putrescent manures that could be produced on the farm, and by plaster, clover and peas, and the best possible rotation. This is a strong assertion, but such a farm has certainly never come within our observation. We do not speak of crops, on particular fields, or parts of fields, on which all the putrescent manures may have been expended, but of entire fields, and farms, all brought under cultivation, and the average crops taken for a series of years. From this sweeping remark must, of course, be excepted some of the alluvial lands on James river and elsewhere which are known to have been very highly improved by a judi-cions system of cultivation, aided by lime, clover and plaster, and putrescent manures. The farm at Coggin's Point, of the improvement of which, under the management of its two most judicious and energetic proprietors, we have an authentic report, can barely claim exception. And this partial success only confirms our views when we are informed that a portion of this farm, at least, consisted of originally rich land, and that the improvements were made, to a considerable extent, by marl not very unlike that of the Pamunkey. We find, from the table on page 184, that its average product in wheat for the first fifteen years of marling, was 8.22 bushels per acre, and during the last series of sixteen years was 12.10 per acre—the crops increasing consi-

* In connexion with this subject we append to this review an interesting letter from Robert W. Tomlin, Esq. of Hanover county, containing some valuable statistics as to the effects produced by the cocene marl in the neighborhood of Newcastle,

derably towards the close of the series, the last crop having been 16.81 per acre. Now it is not denied that these crops are much greater than could ever have been realized from any amount of putrescent manures alone, and with our valuable and effective labor, they were highly remunerative; but as we shall attempt to show, in the sequel, they are not equal to the products that may be reasonably expected from the poorest lands of Eastern Virginia in one-fourth the time by the use of calcareous manures as the basis, together with other necessary mineral and enriching manurcs that may be applied with much less labor and expense than have been incurred in making the improvements on this farm. It is impossible, we think, that we can be mistaken in these views, if any reliance is to be placed on our own experience and careful observation, and on those principles of agricultural chemistry that are now undisputed and recognised by all men of science, of every shade of opinion, as established truths.

These admitted truths being the basis of our reasoning, and often referred to, we desire the reader to bear in mind. They are the following:

1st. That all cultivated plants consist of certain organic and inorganic elements, which in all healthy plants, of the same species, preserve nearly invariable proportions.

2d. That the organic elements are carbon, oxygen, hydrogen and nitrogen.

3d. The inorganic consist of various mineral substances, such as soda, potash, magnesia, lime, phosphoric acid, &c. found in invariable proportions in the ash of the grain and stalks of plants of the same species, varying in plants of different kinds, but deemed essential in proper proportions, to the healthy existence of all plants.

4th. That the organic elements are derived chiefly from water and atmospheric air and the inorganic entirely from the soil.

In the twenty-fourth chapter we find many ingenious and plausible arguments in support of new doctrines, in some measure inconsistent with the views just indicated, and from most of these doctrines we must, with all due deference, express our dissent. We think that nearly every difficulty suggested by our author is susceptible of easy explanation, on principles first announced in this country by himself, or since ascertained by others, and now admitted to be chemical truths. We shall refer to acknowledged principles, without encumbering our pages with numerous authorities, taking it for granted that those who follow us in these investigations will not only examine closely the work of our author, but also the writings of the modern agricultural chemists.

The chapter discusses "other fertilizing powers and effects of calcareous earth" under the following heads, to wit: "1st. Causing the more rapid decomposition and perfect solubility of vegetable matters, otherwise inert or insoluble; 2d. Enabling either the soil, or the

plants growing thereon, to draw from the atmosphere greater supplies of manuring or alimentary principles, namely: 1st. Carbon, to growing plants; 2d. Azote (nitrogen), from the atmosphere, through the instrumentality of leguminous plants; 3d. Nitric acid, and nitrates, to the soil, and thereby increasing the supplies of azotic principles to growing plants." It is not our purpose to argue in favor of any peculiar theory of vegetation, nor to become the partisan of any particular school of chemists. Our wish is to reconcile agricultural phenomena with known and established principles; and when a cause sufficient to account for a given effect is ascertained to exist, we deem it true philosophy to be content with that, without speculating as to other possible causes.

Our author in referring to the solvent power of potash and soda, and, by analogy, of calcareous earth, in reducing inert vegetable matter to a condition in which organic manures may be absorbed by the roots of plants as food, brings into collision two conflicting schools of chemists, maintaining opposite opinions with much show of reason on both sides; and so far from establishing a theory on solid grounds, only opens a wider field for controversy. The action of carbonate of lime and of the alkalies and alkaline earths, in neutralizing acids, now known to exist in most soils, and to be generated in the process of vegetable decay, in all soils, and admitted to be poisonous to plants, seems to us to be a key at once to every difficulty. Walk with us into the laboratory of Nature for a few moments, and we will endeavor to make these matters plain. Observe this new ground; it was cleared three years ago of a growth of oak, hickory, dogwood and chestnut. It is what is described in the Essay as "free light land," capable of producing about twenty bushels of corn to the acre, when first cleared; it has not been limed. Two years ago it was in wheat, very roughly ploughed in after the first crop of corn, and dressed with one hundred pounds of Peruvian guano, and yielded eighteen bushels of wheat to the acre. Observe the stumps, especially of red oak; around each is a vigorous growth of sorrel, interspersed with the decaying fragments of the wood that fall from the stumps as the decay goes slowly on. This land, now covered with weeds, would not without lime produce half a crop of wheat; not because it is poorer in vegetable matter than before, for it is, in truth, richer in that respect, but it is decaying, and not decayed vegetable matter, and the acid that arrests the decay also poisons cultivated plants. Observe the adjoining piece of land cleared a year or two earlier-this has been limed—the sorrel has nearly disappeared, and a vigorous growth of red clover has taken its place. Go with us now into that extensive field of black low ground. Ten years ago the larger part of this field was almost destitute of grass, and the little that appeared among the coarse weeds seemed to have no hold on

the earth, but might be scraped off with the sole of your boot. It was not then drained, and abounded with slowly decaying but not decayed vegetable matter, and was spongy and puffy. If in wheat, half the crop, at least, would be winter killed, and the remainder would yield a scanty product of shrunken grain on straw with scarcely strength to stand up. It has been drained and limed; you see now every spot is thickly covered with beautiful clover, with now and then, in the wettest parts a sprinkling of sorrel. It is now firm to the tread, and produces heavy crops of corn and wheat without guano. Observe this little peninsula, nearly surrounded by ditches-this was the head of a gum swamp, so shaded that the vegetable matter in it was nearly peat. Upon being exposed to the sun and air it became sufficiently decomposed to produce corn. Wheat was attempted but was destroyed by sorrel, the result of the acid generated by the slowly decaying peat. It has not been limed. It will be sowed in oats after corn, and not having lime at hand, we shall dress it with ashes, which will neutralize the acid, and 'at the same time furnish the potash necessary for the immediate use of the oat crop. Now what is the philosophy of all this? Decay (or eremecausis) is nothing more nor less than slow combustion, and the dust, which is the final result of complete decay, is precisely the same in its chemical elements with the ash of the same vegetable substances, yielded by burning with fire. And it is not until this process of decay becomes complete that any portion of the inorganic food of plants is furnished. Acids of all kinds arrest or retard decay, and water, in excess, has the same effect. Now when the lands, which we have just visited, were drained and limed, the checks to decay were removed, the vegetable matter in the soil, in the presence of heat and atmospheric air, proceeded, without hindrance, in the natural process of decay, until the inert matter was reduced, in a great measure, to its ash, and furnished a large portion, at least of the mineral elements required for the perfection of the cultivated plants; and the soil relieved of its redundancy has become firm and sound. It does not follow, because reduced to its ash, that all this vegetable matter has been destroyed; its mineral elements, except such parts as have been consumed by the crops, remain still in the soil for future use; and the ammonia, which existed in combination with the vegetable matter, though set free by the operation, is not dissipated, but is retained by the absorbency of the earth, or enters into new combinations in the soil, and is preserved until used up by the growing plants, as explained by Johnson in his lectures .- (410-11.) The crops, however, being greatly increased by the process of liming and draining, have consumed a much greater amount of the necessary elements found in the soil, which must of course be restored, to keep up the fertility of the land,

The remarkable effect of calxing on the rich neutral soils of James river, of which a new explanation is attempted in this coapter, may, we think, be sufficiently accounted for, by the necessity of lime to neutralize the acid generated by the decomposition of the immense mass of vegetable matter accumulated on these lands under the enclosing system. And if further explanation be required it may possibly be found in the effect of clover acting as a "fibrous manuring" on calcareous soils, to which we shall have occasion hereafter more

fully to refer. On the second head of this chapter, "The effect of calcareous manures in drawing increased supplies of nutriment from the atmosphere," our author does not appear to write with his usual precision, or to reason with the clearness for which be is distinguished. Thus he says, page 243, "This question is, if the atmosphere always contains all the organic constituents of plants in inexhaustible quantities-and if plants derive from the atmosphere nearly all of their constituent parts-why should they ever suffer for want of a sufficient supply of nourishment, whether growing on rich or poor soils? The answer is, that the laws of nature forbid some of these gaseous bodies to be taken up directly by growing plants-or, at least, only under certain conditions; and these conditions are not dependent on the quantities of these gases present in the surrounding atmosphere, and are but slightly under the control of man, limited in know-ledge as at present." We do not see how we are advanced at all in this investigation by reference to the laws of nature, which is a mere re-affirmation of the general fact to be explained, and which fact may be explained with entire satisfaction by referring to another fact, admitted by all agricultural chemists that even though all the organic constituents of plants were furnished by water and the atmosphere, the inorganic, though less in quantity, are quite as essential, and must be supplied by the soil. Nearly all the elements of an egg may be in the food of a hen, yet if denied lime to form the shell, she cannot lay a perfect egg. Again he says, "Thus the smallest but richest element, azote, would seem to be obtained by plants principally, or entirely, through their roots, and from the soil. Therefore, the supply to plants is in no degree increased by the prodigious quantity of azote in the atmosphere." This is plainly a non sequitur, besides being directly opposed to the experiments of Boussingault, detailed under the next head, and adopted by our author; and also, in conflict with the teachings of Liebig, Petzholdt, and a number of modern agricultural chemists, who, whilst they deny that the nitrogen of the atmosphere is ever taken up by growing plants, yet maintain that the ammonia, which is always present in the atmosphere, is the principal, if not the only source of the supply of nitrogen (or azote) to plants. (Liebig, Organic Chemistry, 146. Petzholdt, Lectures, 57.) We do not

mean to take sides in this controversy, or to express an opinion as to the source of the azote of plants, a matter, in our view, yet requiring elucidation. Again he says on page 247, "The foregoing views seem to offer the only plausible explanation of that great mystery of vegetable life, that plants on barren land should pine or starve when surrounded by unlimited supplies, in air and water, of their necessary elements." Now this is no mystery at all, if by barren land is meant a soil entirely destitute of the necessary inorganic elements of plants, which can be derived from the soil only. And if by that expression is meant soils destitute of vegetable matter, the statement is not consistent with facts, said to be well attested, of soil, rich in minerals, continuing to produce large crops of grain, though destitute of vegetable matter, and never manured; as is said to be remarkably the case with the land in the neighborhood of Naples, which is kept rich, under continual cropping, by the disintegration of the minerals of which it is composed. Again he says, "If then we suppose that the very small proportions of necessary salts, found in the ashes of plants, are already in the soil (as is generally the case,)" &c. Now this is a supposition by no means to be made, because not consistent with well established facts, and indeed the contrary bas been demonstrated in the "Essay," in regard to one, at least, of these necessary salts, time, which has been shown to be almost entirely wanting in the poor lands of Eastern Virginia; and we have no doubt that these lands are equally deficient in nearly every other necessary inor-ganic element. The evident confusion of the author, in treating this part of the subject, arises, we think, from his attaching too little importance to the inorganic portions of plants as a necessary part of the vegetable economy. Johnson, who is no disciple of Liebig, speaking of the presence of the inorganic elements in different plants, in definite proportions, ac-cording to their different kinds, says, "They are constant on every soil, and in every climate; they must, therefore, have their origin in some natural law." "A doubt can hardly remain that this inorganic matter forms an essential part of their existence and that they cannot live without it." (Lecture, 179 and 181.) Johnson says, again, "If one of these necessary inorganic forms of matter be rare, or wholly absent, the crop will as certainly prove sickly or entirely fail, as if the organic food, supplied by the vegetable matter of the soil, were wholly withdrawn. It is, therefore, as much the end of an enlightened agricultural practice to provide for the various requirements of each crop, in regard to inorganic food, as it is to endeavor to enrich the land with purely vegetable substances." We have been somewhat amused at the seriousness with which our author and Dr. Wight have put forth their facts and reasonings with regard to the supposed peculiar effect of carbonate of lime, as enabling plants to draw more carbon

from the atmosphere. It is only another evidence in addition to the great many furnished by the annals of science of the facility with which even the acutest intellects may be deceived by appearances when in the ardent pursuit of desired results. All these facts and reasonings may be conclusively answered by the general affirmation, that whatever tends to increase the growth of the plant enables if to draw an increased supply of carbonic acid from the atmosphere. For it being conceded that about fifty per cent. of all plants consists of carbon, and that all, or nearly all, of the carbon of plants is derived from the carbonic acid of the atmosphere, it is obviously impossible that the growth of plants can be materially increased by manure of any kind without causing a greater absorption of carbonic acid from the atmosphere. And the very ingenious and elaborate experiments of Dr. Wight amount to no more than this. Doubtless if he had tried a weak solution of guano or liquid manure from the stable, instead of carbonate of lime, his experiments would have been much

more strikingly successful.

The facts, stated on page 253, as to the deterioration in the growth of wheat and other crops in the neighborhood of those, growing on limed and plastered lands, may be explained upon nearly the same principle. We may remark that a similar fact is frequently observed and commented on by farmers who use guano on wheat. So much so, that it has now become a subject of common remark among overseers and others, who say that "the land is insulted by guano," and that rich cow-pens, alongside of guanoed wheat, will now scarcely produce a tolerable crop. had ourselves attributed this apparent fact to contrast, but it may possibly be literally true. The supply of carbonic acid in the atmosphere is in limited quantity, and the air may be enriched by adding a considerable portion of carbonic acid, thereby promoting greatly the growth of plants. This process, which, of course, is artificial and on a small scale, shows that the supply in nature is not adequate to the demand, and as plants consume it in direct proportion to their bulk, it must follow that lime, guano or any other manure that increases the growth of plants, without increasing the supply of carbonic acid in the atmosphere will, of necessity, enable the plants, thus rendered more vigorous, to deprive the weaker in their neighborhood of some portion of the already insufficient supply of carbonic acid; and thus the smaller would be impoverished by the larger, just as weak cattle, in a lean pasture, are impoverished by those stronger than themselves.

The effect of calxing, in the improvement of land, by enabling leguminous plants to draw nitrogen from the atmosphere, as illustrated by the experiments of Boussingault, requires further examination before it can be adopted as ascertained truth. Johnson questions the certainty of Boussingault's experi-

ments, whilst Liebig, as we have already seen, denies the possibility of any portion of the nitrogen of the atmosphere entering into the constitution of plants, whilst he affirms that the atmosphere is the abundant source of the nitrogen of plants in the ammonia which is always present in small quantity and conveyed to the leaves of plants in dew, and to the roots in rain and snow water.

The views presented in regard to the power of calcareous soils to attract nitric acid, upon the principle of the artificial nitre beds of France, open a new and interesting field of inquiry, as yet but little explored. The facts, when ascertained, will go far to explain the remarkable manuring effects of shade, whether by clover or other "fibrous" covering. In Allan's "American Farm Book" there is an article on "Gurneyism, or Fibrous Manuring," in which most extraordinary effects are ascertained, by actual experiment, to have been produced by a simple covering of straw, and the results explained on the authority of a communication in the "British Farmers' Magazine," upon the principle of the formation of nitrates, as is done in the artificial nitre beds of France. It is stated upon this authority that grass, simply covered with straw, vielded six times as much as that not covered, and five times as much as that dressed with guano and other rich manures. These results were ascertained by repeated and most careful experiments, and no doubt is expressed of their entire accuracy. The manuring effect of clover, which, according to Boussingault, is out of all proportion to the quantity of vegetable matter contained in it, may probably be also accounted for on this principle. Dr. Robert Baldwin of Winchester, maintains, with great earnestness, that the sole manuring virtue of clover consists in its capacity to shade the land. He has maintained the principle of "fibrous manuring," without, perhaps, ever having had his attention drawn to the facts or reasonings by which it has been sustained in Europe. He maintains that clover is in no degree dependent for its fertilizing effects on the vegetable matter contained in the crop, but that it may be removed, root and branch, after it has performed its office of shade, without any diminution of fertility. Dr. Baldwin's views have generally been regarded as extreme, and we do not mean to endorse They have certainly new interest in connexion with these recent developments, and their author being a gentleman of undoubted intelligence and observation and a successful practical farmer, his facts and opinions are at least entitled to respectful consideration. We have now under our view the most striking evidences of the effects, on a large scale, of simply covering fields, in grass, with straw, which are vastly beyond any results that could possibly be attributed to the mere manuring effect of vegetable matter.

adopted as ascertained truth. Johnson questions the certainty of Boussingault's experitions the certainty of Boussingault's experitions the certainty of Boussingault's experi-

it just to make, on the new doctrines contained in the 24th chapter, we proceed, in the further execution of our task, to offer some observations on subjects, which, if not so new or interesting, are at least of equal practical im-

portance.

There are two offices performed by calx in soils now no longer a matter of doubt, which, independent of any other actual or supposed effects, make it of inestimable value. These are, that it neutralizes acids, now known to exist in all our poor soils, and that it furnishes one of the essential inorganic elements of cultivated plants. These alone are sufficient to satisfy any reflecting farmer of the indispensable necessity of calxing his land, and the practical question presents itself, what is the cheapest and best mode of effecting this operation? And intimately connected with this question the farther inquiry, what is the necessary and proper quantity of the material to be applied?

That calx has generally been applied in excess, as well in this country as in England, we have no doubt, and nothing but the very humid climate of England and the large quantities of vegetable manures applied in that country, in every form, has preserved it from utter sterility under the enormous dressings of lime that we learn from all her writers, ancient and modern, have been applied. The later practice of her farmers seems to be tending to a more rational system. In Virginia as small a quantity as fifty busbels of slaked lime to the acre has, in some cases, been found excessive. The Messrs. Harrison of Brandon, as we learn from a communication in the Farmers' Register, found seventy bushels to the acre entirely too much, and in their subsequent large operations reduced this quantity to thirty-six bushels. In France, whose climate and soil are very similar to ours, a very small dressing, even as little as eleven bushels to the acre, as we learn from Puvis, have been found sufficient for a single application. This practice, where the true office of lime is understood, is founded on the principles not only of science, but of common sense. Lime in the soil acts as a food and a medicine. Your horse requires a gallon of grain to-night, you do not put in his manger a bushel in addition, to save the trouble of feeding him for the next four days. You suffer from a fit of indigestion-you know, from experience, that a few grains of carbonate of soda, lime, or magnesia will neutralize the acid generated in the stomach, which retards digestion and is the cause of your annoyance. You do not take a quarter of a pound, lest some days hence you may suffer from the same cause of annoyance. Now as essential food for growing crops, it is ascertained that a very small quantity of lime is required. A crop of wheat, both straw and grain, producing twenty-five bushels to the acre, consumes less than nine pounds of lime, and one bushel, if it could be applied in such manner as to be all available,

the crops in a full rotation of five years. Its effects as medicine can only be ascertained by close observation; and as the physician watches carefully his patient, and applies his remedies at every recurrence of the symptoms of the disease, so the enlightened farmer, by carefully noting the indications, may prescribe, with success, for his land. These opinions are not mere deductions from theoretical knowledge, but the result of long experience and the closest observation. We have had land in our own practice injured temporarily by fifty bushels of lime to the acre, and a small picce excessively dressed with shell lime, entirely effete, so damaged that it has not recovered under considerable applications of putrescent manures in more than twenty years. In the last few days we have walked over extensive fields, limed under our own eye, during the last fifteen years. The quantity applied was fifty busbels on the alluvial lands, chiefly black soil abounding in vegetable matter, and from fifty down to twenty-four bushels, on the "forest lands," such as are described in the Essay as "free light lands." The effect has been carefully noted, and but one portion of all this land gives any indication that more lime is required, and that is about twenty acres of the black land, somewhat wetter than the rest, for which, two years ago, we prescribed fifty bushels of lime additional to the acre, which was applied, and now, although well set in clover, a sprinkling of sorrel indicates the presence of some acid. In the "forest lands," where but twenty-four bushels to the acre were applied, we have observed that around the red oak stumps the decaying wood, (which, according to Liebig, contains at least 50 per cent. of humic acid,) has been entirely decomposed, and the sorrel, which was for-merly matted about them, has given place to a firm sod of greensward. We conclude that more than fifty bushels of slaked lime to the acre at one application is never advisable, and that twenty-five bushels are more frequently quite sufficient, and that reliming, even at this small rate, will not usually be required for a number of years.

Slaked lime is delivered on the rivers at seven to eight cents a bushel. The cost of hauling so small a quantity as twenty-five bushels to the acre, upon the estimate of marling expenses by Mr. Ruffin, presently noticed, would be, even for considerable distances, so trifling as not materially to add to the expense.

in the stomach, which retards digestion and is the cause of your annoyance. You do not take a quarter of a pound, lest some days hence you may suffer from the same cause of annoyance. Now as essential food for growing crops, it is ascertained that a very small quantity of lime is required. A crop of wheat, both straw and grain, producing twenty-five bushels to the acre, consumes less than nine pounds of lime, and one bushel, if it could be applied in such manner as to be all available, is more than would be required as food for all

in the price of labor. The results attained by apply to marl rich in phosphate and sulphate Mr. Ruffin were most extraordinary and are attributable only to his own peculiar energy and exact method, and to the great efficiency of slave labor, when properly directed. Without being familiar with the peculiar details of marling labors, we venture the assertion, that in no other case, under the most favorable circumstances, has any thing like the result attained by him been accomplished by any other person. By the table on page 351, we learn that his labors on a large scale resulted in hauling one hundred bushels of marl, weighing 105 lbs. to the bushel, half a mile from the pit to the field, at a cost of 24.46 cents; and including all other expenses, of digging, spreading, &c. costing on the field less than 54 cents the hundred bushels. It will be observed that the cost of hauling half a mile is less than one-fourth of a cent a bushel, or less than four and a half cents for 1890 lbs, a full load for two mules. Now we venture to say that in any part of the world, out of the slaveholding States, the same work would cost four times the money, and yet we are constantly reproached with the inefficiency and expensiveness of slave labor. We find in Stephen's Farmer's Guide, Vol. II. 669, some estimates of the expenses of marling in England, where wages are said to be at a very low point. In these estimates the cost of hauling a load of forty bushels of marl one mile is rated at three shillings and six pence sterling, or about eighty cents, or two cents a bushel for one mile, and one cent for half a mile-just about four times Mr. Ruffin's estimate. But, as we said before, we think Mr. Ruffin's estimate much too low for operations, even in Virginia, as they may be expected to be conducted under the best common management. In illustration of this, we append a letter from Mr. Charles B. Williams, Recording Secretary of the Virginia State Agricultural Society, furnishing many valuable statistics on this subject.

The cost of marl, if it were fourfold greater than it is, would be fully justified by the profits that accrue from it. Our object is not to dissuade persons from its use by magnifying the estimate of its expense, but to furnish true data from which the relative cost of calxing with lime or marl, may be properly estimated. It is obvious that the advantage of one over the other depends mainly on distance, as the principal expense is incurred in the hauling. When the marl is rich, easily accessible, and not distant, say not over a mile, marling would probably be cheaper than liming. At a greater distance than one mile, unless the marl contain some other fertilizer than carbonate of lime, lime would, no doubt, be cheaper. Twenty-five bushels of slaked lime, in the state of in robust health, with hope revived, to comfine powder, in which it is applied, is, no mence again his labors among us, or broken fine powder, in which it is applied, is, no doubt, fully equal, at least, for early effect, to one hundred bushels of marl, containing 80 per cent. of carbonate of lime, as it is usually found in undissolved shells, and frequently in indurated masses. These observations do not

of lime, and possibly other enriching matters of such value as to bear carriage to great distances. And some of the Pamunkey marl, with even as little as 10 per cent. of carbonate of lime, yet abounding in other valuable matters, may, upon the principles we have endeavored to illustrate, yet be found of much greater value than they have heretofore been supposed to possess; thus Prof. Gilham of the Virginia Military Institute, is said to have ascertained, by analysis, that some of these marls contain as much as 18 per cent. of sulphate of lime, besides the phosphate and other valuable matters. We have never seen any farm on which these marls have been used, put under an ameliorating system of cultivation, yet we have no doubt, from what we have observed of their effects on farms in the neighborhood of Hanover Town, that they would be productive of the highest degree of fertility if a milder rotation were adopted in lieu of the scourging system of cultivation now common in that neighborhood. Indeed if any reliance is to be placed in an experiment carefully conducted by Petzholdt, and reported in his lectures, (page 99,) the soil would not only have the benefit of this manure as gypsum, if in that form it has any peculiar value, but the sulphate of ammonia would be largely formed in the soil, and the sulphate of lime actually converted into the carbonate, so that in this view these marls, even for the mere purpose of calxing, have a much greater value than has been heretofore attributed to them.

We had wished to present some statistical views of the improvement of lands in Eastern Virginia, since the publication of the "Essay," and which are mainly due to truths first promulgated in that work, and enforced by its author and his correspondents in the pages of the Farmers' Register, so long and so ably edited by him. But our limits forbid it; and indeed, statistics are scarely necessary in proof of a fact of which we have evidence on every side. We see it in the renewed hope and enterprise of our people; in the increase of wealth, public and private; in the improved condition of our schools and colleges, which thirty years ago were like "banquet halls deserted," but now are crowded with ingenuous youths, chiefly sons of thriving farmers, in earnest pursuit of that knowledge which at once secures and constitutes the true riches of a republic. We see it in the improved aspect of the countryin the old hearths, once desolate, now cheerful and happy-in the increased commerce of our cities, and in the renewed beauty of our lovely villages. Every citizen who has been induced by care and disappointment, he returns from his wanderings to lay his bones quietly with his ancestors, is a living witness of this gratifying fact.

The most important part of our duty remains

yet to he performed. We have now to fulfil our promise to the cultivators of poor lands, to point out a plan hy which they may speedily, cheaply and certainly render their farms productive, and themselves, if not rich, at least independent. This, we have the pleasure to say, is an easy task, yet we would not venture upon it, and incur the hazard of being classed among empirical pretenders, if we did not know that the plan suggested is founded in the true principles of nature and of science, and has been sufficiently tested by actual experience. It consists in correcting in the soil whatever is injurious to vegetation, and in giving to it all those elements necessary for the growth of plants, which science teaches, are derived

only from the soil. The prescription is for poor lands, and it applies to all dry lands from the mountains to the sea, let their poverty be ever so extreme, provided they are not precipitous, have a sound subsoil, and do not contain more than 95 per cent. of sand. Alluvial lands are not embraced, for though in many cases unproductive, they cannot be called poor, and their improvement demands a somewhat different treatmentembracing a system of careful drainage. The lands, more particularly within our view, are such as the originally thin and thoroughly exhausted "forest lands" of the Northern Neck and the counties of Essex, Middlesex, King William, part of King and Queen, and Caroline, and all the counties below tide-water, of similar geological formation. These lands in their most reduced condition, produce scarcely a barrel of corn to the acre, and no wheat, and where turned out to rest, are covered with a scant growth of poverty-grass. Few entire farms are in this condition—the most neglected having small spots of improved land. We suppose our plan, however, to be applied to a farm on which there is no spot improved, and all reduced to the lowest possible condition. Yet we would guarantee that in the short space of five years, the average crop of wheat shall be brought up fully to that attained at Coggins' Point in the last sixteen years, of a period of marling alone, extending back more than thirty years; and that all the expenses of the improvement shall have been paid out of the crops, and if the proprietor has been industrious and economical, the price of the farm paid besides; and that in the next five years the average product in wheat shall he so much greater than that attained at Coggins' Point that the whole expense of manuring and harvesting shall he paid out of the surplus, and the average crop of Coggins' Point he left as clear profit. And though our experience does not extend thus far, we have no doubt that in another round, or two rounds of crops at farthest, the product of this poor land shall be found at least equal to the highest average on the richest and most highly improved farms in the State. This seemingly wonderful result is to be produced by adding to the effects of

yet to be performed. We have now to fulfil fluence of Peruvian guano, aided by a judiour promise to the cultivators of poor lands, to cious rotation, proper culture and due attention

to putrescent manures.

The arable land should be divided into five equal parts, separated by fences or not, as may suit the convenience of the proprietor, and the fields cultivated in the succession of coin, wheat, clover, wheat on fallow, and pasture: every grain crop to be manured, and the land to be calxed with twenty-five hushels of lime to the acre, or its equivalent in marl, as the fields come successively in corn; the composts and well rotted manures to be applied to the corn in the hill; and if the supply is insufficient to dress the whole, the deficiency to be made up with guano, at the rate of one hundred pounds to the acre, applied either when the land is broken, or after the corn is thinned, . and just before the dirt is thrown to it. The manuring of the corn in the hill is a great saving, and pays a handsome profit on the manure, but is not relied on as a means of improvement. The wheat, on both corn land and fallow, to be dressed with two hundred pounds of Peruvian guano to the acre. corn-field wheat to be sowed in clover. The surplus straw to be applied as a top-dressing to the young clover, if it can be applied soon after harvest; if not, to the field that had been in fallow wheat, and that will be next in pasture. Let no hogs enter the fields, unless for gleaning; and limit the amount of stock of all kinds to the actual necessities of the family. If this plan is strictly adhered to in every round of crops, and the lime repeated, should the appearance of sorrel indicate the presence of acid, we regard the result predicted as absolutely certain. When first taking possession of a farm so poor as to he reduced below the sorrel point, it may with great profit be all fallowed, dressed with guano and put in wheat. Such lands have in the first crop yielded enough to pay all expenses and the purchase money of the farm. But it will not do to repeat the wheat crop without previous calzing, as the sorrel will destroy it. These results are cer-tain and speedy. They are also cheap. For although the plan requires the annual outlay of money, yet the capital is certain to be returned, with more than 50 per cent. profit at the end of the year, whilst the land progressively improves. The beauty of this system consists in the facility with which it may be accommodated to the circumstances of farmers of every degree. The rich and the poor, the owners of slaves and those who have none, the tiller of fifty and the tiller of five thousand acres may all equally avail themselves of its advantages. All that is necessary to insure success is faith, energy, perseverance and a little capital, or if that be wanting, reputation for integrity, which, for such a purpose, will certainly command it.

the richest and most highly improved farms in the State. This seemingly wonderful result is to be produced by adding to the effects of calcareous manures the still more striking in-

and while it has given us peculiar pleasure to do justice to the distinguished merits of our author, we have not hesitated to express, with the candor which we know he would both practice and approve, our dissent from such of his doctrines and reasonings as we deemed erroneous. It is not at all improbable that in pointing out his supposed errors of opinion upon questions purely scientific, we may have fallen into much greater errors ourselves, Our main purpose has been practical. We believe the team of our author both sure and strong, yet we think he drives rather too slow a coach for this go-ahead age. We desire to accelerate the motion, that agriculture may keep pace with other industrial pursuits. And for this purpose we earnestly recommend the use of such additional means as we feel sure will accomplish the end in view. We wish to see the tide of emigration not only checked, but arrested, by convincing the people of Virginia that there is no necessity to leave the homes of their ancestors in order speedily to better their condition. Some are yet distrust-We occasionally see one who, apprehending that his family may want, is casting a wistful look towards Texas or California, or what is still worse, towards Washington. To all such we would speak a word of encouragement. Be of good cheer; "Put thou thy trust in the Lord, and be doing good: dwell in the land, and verily thou shalt be fed.'

Ditchley, February 21, 1853.

HON. WILLOUGHBY NEWTON:

My Dear Sir,-Yours, post marked 12th, reached me on the 18th of this month, and I most cheerfully comply with your request, to wit: "to give you a statement of the improvement of my father's land, since the division among his heirs," and also send you some valuable statistics of marling, attained by one of my immediate neighbors, Mr. Carter Braxton, whose estate lies on the Hanover side of the Pamunkey river, and immediately opposite to my father's land, in the county of King William.

My father's estate was divided among his heirs in 1831. At that time, my younger brother, Col. H. B. Tomlin, and myself were minors. Four portions of the estate (all that part lying in the county of King William,) were cultivated as one farm, under the management of the late most estimable and excellent Gen. Corbin Braxton-our guardian. the estate, under his direction, was judiciously managed, I need give you, at least, no assurance. The land was thoroughly cultivated, and drained as rapidly as circumstances would permit. All the putrescent manure, both stable and barn-yard, that could be made, applied to the land in good time; while the poorest spots, well covered with partially rotted straw and chaff, had the cattle penned on them during the summer months. The farm was cultivated on the usual exhausting three-shift and grazing

course of that time. With all the General's known skill and good judgment ever displayed in the general details of farming, he was only able to keep the corn crop of the farm stationary, while the wheat crop diminished yearly, (even on the highly cow-penned spots the wheat always tumbled and was badly rusted,) until it was a nice question whether the wheat crop paid expenses of cultivation. In the year 1838, the farm was divided into three farms, and each of the three put under the four-shift system in 1839. Before the year 1838, some marling had been done in spots, at about one hundred and fifty bushels to the acre, which mail proved to be very poor in carbonate of lime. The scourging rotation of three grain crops in four years proved with us improper, as the wheat on the fallow field, not marled, was so damaged by sorrel as to bring the average below the yield of the corn-field wheat, and even on the few marled spots, where only a bunch of clover could be found, this was so closely grazed by the stock as to give but a very poor yield in comparison with results since obtained from clover fallow under the present five-shift system. The necessity of having a pasture and the sorrel together drove us into the five-shift system in 1843. Between 1838 and 1843 we made greater exertions in marling yearly from the banks we use at this time-the blue eocene marl; that used prior to 1838 being the grey eocene marl. Not till 1844, did we succeed in marling a whole field in a season. Since 1842, I have never failed to have a good stand of clover, and a good growth sufficient to mow. In 1848, we commenced sowing the field pea in our corn crop at the last working, and have continued to sow it up to this time.

The wheat crop on the land I now own, in 1838 averaged 31 bushels per acre.

The wheat crop on the land I now own, in 1851 averaged 244 bushels per acre.

The wheat crop on the land I now own, in 1852 averaged 21 bushels per acre, notwithstanding the fresh of the river in the last of April covered two-thirds of the land, and so damaged one-third as to yield only 11 bushels per acre.

The corn crop of 1838 averaged 20 bushels

per acre.

The corn crop of 1850 averaged 55 bushels

per acre.

The corn crop of 1852 averaged 371 bushels per acre-damaged by fresh in April, killing my corn, baking my land, had all to be reploughed and planted just before harvest.

On Col. H. B. Tomlin's farm, wheat crop of 1838 averaged between 2 and 3 bushels per

acre.

Wheat crop of 1851 and 1852 averaged between 24 and 25 bushels per acre.

Corn crop of 1838 averaged 15 bushels per

Corn crop of 1851 and 1852 averaged 35 bushels per acre.

On my sister's (Mrs. Coulton) farm, man-

aged by Col. H. B. Tomlin, wheat crop of as I learn from bricklayers, dirt diggers, team-1838 none sowed-oats substituted.

Wheat crop of 1839 averaged 3 bushels per

Wheat crop of 1851 averaged 28 bushels per acre.

Wheat crop of 1852 averaged 20 bushels per acre. Corn crop of 1838 averaged 171 bushels per

Corn crop of 1852 averaged 40 bushels per

Mr. Carter Braxton's estate, wheat crop in 1840 averaged not quite 3 bushels per acre.

Wheat crop in 1851 averaged 18 bushels

Wheat crop in 1852 averaged 15 bushels per acre. Some 60 or 70 acres very much damaged-some producing nothing-from the fresh of April.

Corn crop of 1840 averaged 191 bushels per

acre.

Corn crop of 1852 averaged 50 bushels per acre.

Since 1842 the wheat crops and corn crops have steadily increased on each field in the

rotation over the preceding crops.

Now, my dear sir, since without marl our lands will not bring clover-since without marl our lands would not yield a growth of pea vine sufficient, in a growing corn crop, to be of benefit to pay for the peas-since without marl the five-shift system will not answer, as the sorrel destroys the wheat on the fallow field, am I wrong to give to marl the credit of being the true and only basis of this increase of product? Before marling, the more sandy soils, when not under cultivation, naked and liable to be drifted by high winds in very dry weather, while the stiffer soils presented little in their growth, save poverty-grass, sorrel, and the running blackberry brier. After marling, our fields in winter covered with dark weeds and in the spring with luxuriant red clover, and when this should fail, (from bad seeding, even on a few feet square,) a certainty of seeing a verdant turf of the white clover. Of marl, and its benefits, I should never have known anything, but for the Essay on Calcareous Manures, by my much esteemed neighbor and friend, Mr. Edmund Ruffin, which you propose to review. In haste,

Very truly, yours, Ro. W. Tomlin.

Richmond, February 18, 1853.

HON. WILLOUGHBY NEWTON:

My Dear Sir,-I received your esteemed favor of the 11th instant on yesterday, and having availed myself of the means of information within my reach, I now proceed with pleasure to answer your inquiries. The daily hire of a cart, with two mules and a driver, when engaged in continuous labor in any of the departments you mentioned, is, and has been for a number of years, \$2 50 per day, Col. Randolph, I have estimated the expense

sters on the streets, &c .- the driver being an able bodied man, capable of loading and unloading with facility and dispatch. For removing a full load (the standard fixed by City Ordinance at 1500 pounds,) for the distance of half a mile, supposing it to be part of a continuous and large job, the price is 25 cents per load. The price for hauling a load of guano, is 36 cents from Rocketts, say three-quarters of a ton. For wheat there is no price current—the millers having for several years received that article at the landings and depots free of the expense of hauling to the vendor.

I had a conversation with Col. T. J. Randolph, an extensive railroad contractor, who being requested to furnish for the State Engiueer an estimate, founded on his experience, of the actual cost per day of a one horse carthorse and driver, with a yearly addition to the actual expenses of a reserved fund sufficient to reproduce the permanent capital; that is, the horse in 6 years and the cart and fixtures (I think) in 5 years—entered into the following minute calculation, founded on these elements:

ESTIMATED COST OF CART, HORSE AND DRIVER.

A cart and gear cost about \$40. The same, with occasional repairs, will last five years. Allowing 270 working days, 10 cents per day for interest on cost and wear and tear, would be \$27 a year; or \$135 in the five years to repair, pay interest and renew.

A horse will cost \$120. The same will last six years. 10 cents a day will pay interest on cost and renew in six years. Feeding and shoeing a horse, at 30 cents a day, \$109 50 per annum. This amount, for 365 days, is equivalent to 40 cents a day for the 270 working

days.

The driver is usually an inferior hand or boy, hired from \$50 to \$80 per annum. Ave-\$70 00 rage hire never more than

Bread for the same-4 lbs. of meal, at \$3 50, Meat for the same-4 lbs. a week, at

22 88 11 cents, 18 12 Clothing for the same, 10 00 Contingencies,

270 working days, at 50 cts. per day, \$135 00

Summary. Repairs, interest on cost and renewal of cart, per day, Interest on cost and renewal of horse,

per day, Feeding and shoeing the same, per day, 40 50 Cost of driver, per day,

Actual cost of horse, cart and driver, per day, - - \$1 10
In this connexion I will mention that the

daily hire in Richmond for such an equipage as above described is, for continuous labor, \$1 50 per day, with a light boy for the driver. Pursuing the line of calculation suggested by

of a street, or two-horse cart, and a pair of mules and driver, by the standard of Richmond prices, which may serve pro forma as a statement, applicable, with modifications, to every variety of circumstances, which I annex:

Capital Invested.

2 mules, at \$125 each, \$250 00 1 two-horse cart and gear, 55 00

\$305 00

Annual and Daily Expenses.

Yearly int. on cost of mules and cart, \$18 30 Sinking fund to replace mules once in 35 72 seven years, Sinking fund to replace cart and gear twice in seven years, . 15 71

Horse and driver \$125, clothing, sub-185 00 sistence, &c. \$60,

Subsistence of Mules, Shoeing, &c. 40 barrels of corn, or equivalent, at \$3, 120 00 75 00 7500 lbs. of fodder, \$1, 12 00 Shoeing, &c.

\$461 73 Amount of annual expenses, which, if divided by 270 working days, ascertains the daily expense to be equal to \$1 71. Take the items to be carried to the sinking fund, \$35 72 and \$15 71, and multiply them by 7, and they will be seen to produce the ag-

gregate of \$360.

Thus it appears that such an establishment as produces a daily hire in this city of \$2 50, actually costs in perpetuity, \$1 71 per day.— The cost, as per above statement, is \$305; the reserve fund, \$360, which reduced by the purchase of a new cart and gear at the end of three years and a half by the sum of its cost, \$55, leaves the capital entire, at the end of seveu years, for the renewal of the operation for a second series of seven years. I hope this will be found useful, however inaccurate it may be in details, as a formulary which seems to be founded on correct principles, for similar estimates, upon actual expenses. I shall look for your forthcoming review with considerable anxiety, not doubting that it will be a valuable contribution to the cause of agriculture.

CH. B. WILLIAMS.

For the Southern Planter.

LANDS IN AMHERST.

Mr. Editor,—My eye is frequently falling upon notices in the newspapers of Washington and Richmond of sales of land at remarkable high prices, both in the great Valley of Virginia and more recently in some of the counties east of the Blue Ridge. I have just noticed in the Richmond Dispatch, of the 21st of this month, a notice of a recent sale of a farm in Culpeper county at \$35 per acre. In the plication of plaster to each crop, would cause month of November, in passing through the land, if left out a year or two, to cover

county of Albemarle, I had various farms pointed out to me that would bring from \$30 to \$60 per acre; and in quite a mountainous part of the county, and bordering upon the Nelson line, there was a farm pointed out to me as a sample of \$25 land. The owner, who was near by, remarked that he had refused that sum very recently for it. I am well acquainted with the lands from Lynchburg to the Potomac river, and have never yet been able to see why it is that there is or should be such a vast difference in the price of land in the counties of Bedford, Amherst, Nelson, Albemarle, Orange, Culpeper, Fauquier, and Loudoun. In the counties of Amherst and Nelson-and particularly Amherst-land, yes hundreds if not thousands of acres, can be purchased at from \$12 to \$20 per acre, that was originally, and I hesitate not to assert can now be made equal to any of the high lands in any of the counties I have mentioned, by deep ploughing, fallowed with clover, and a liberal application of plaster. The county of Amherst has and must have advantages that no other county in the State can have, viz: there is now a canal running around two sides of it, and in a few years there will be a railroad through its centre, connecting Lynchburg and Charilottesville. And only behold Lynchburg! It is now a city, with more factories and more capital than Richmond itself—that is trying to draw everything in the way of trade into its jaws. I have been a resident of this old free State (as it is familiarly called, from the fact that once upon a time the citizens were so universally in debt that you could not get a single case tried in the county courtbut this is not now the case; this county is as free from debt as any in the State,) for six years, and well do I remember speaking with a large farmer, who was an intelligent gentle-man, as to my intention of seeding timothy, for the purpose of making hay. He and several others remarked that this was not a grass county, and said if I did seed timothy, I would find that it would grow, but would never get up high enough to cut for hay. Fehruary, 1848, I did seed timothy and clover with oats, on flat land—June, 1849, '50, '51 and '52, I cut as good crops of hay as I ever saw cut off of land in the great Valley of Virginia; of the same strength or fertility. All I did after ploughing deep and seeding, was to put on it every January from a bushel to a bushel and a half of plaster, and when I had it, I would add two bushels of ashes per acre. I also seeded English blue grass, timothy and clover upon upland-really red land, and much of it perfectly naked-and in twelve months time I had as nice turf for grazing as you can find in South Western Virginia. This was all accomplished on rented land.

I will also state that I have found that deep ploughing and cultivating the same land two or three years in succession, with a good apitself with the valley or dwarf blue grass and greensward. This has convinced me that all the land in this region wants is deep tillage and some sort of stimulant, and protection for twelve months after seeding, and it will make as good a grass country as any portion of Virginia I have yet seen. If tobacco would get down to one dollar per hundred, and remain at that low price for ten years, Amherst would vie with any county east of the Blue Ridge for grass and stock. But tobacco has been its ruin, and is yet a great drawback to its im-provement. Bushes, briers and broomsedge are the pests of Eastern Virginia. But I have found deep ploughing, heavy harrowing with crooked teeth, if there are many briers, followed with thick seeding of clover and a plenty of plaster, and as little grazing as possible, until a month or two before fallowing, then graze until perfectly naked, if you can before you plough, will make more wheat per acre than most farmers believe can be grown on \$12 or \$20 land.

I had no idea of writing to such length, but have been led on from one thing to another until I have spun out quite a lengthy piece. can easily be proven if necessary.

I. I. Hite. But all I have stated are naked facts, which

Amherst Co. January 23d, 1853.

For the Southern Planter.

SEED CORN.

Mr. Editor,—Thinking over the little article in your March number, from Mr. Noland, upon the subject of seed corn, it occurs to me that my own experience is probably "confirmation strong" of the view he takes. When I purchased my farm, eight years ago, I found upon it a very superior kind of white corn, which had been cultivated here, no doubt, upon the old-fashioned system of five feet by two. I have continued to plant it, but much thicker; and whilst making probably double the quantity of corn upon the same land which my predecessors did, I have observed year after year a manifest depreciation in the quality. Several years since a neighbor of mine recommended and gave me some of his corn, which was very finea large, flinty, white corn. He, I know, practised thin planting. That, too, I observe, under the thick planting system, though upon first quality river bottom land, has considerably deteriorated. At all events, without these facts, I can but think it a matter of no little importance, and shall certainly take some pains forthwith to act upon Mr. N.'s suggestion. I acre, excepting where an equal quantity

should think, however, that a separate patch for seed was more indispensable in your county, where the practice of cutting down corn in the green state is pursued, than in Eastern Virginia, where that is never done, that I am aware of. Apropos of that subject-if you will excuse me for trespassing further upon your time--I should look upon the introduction of that practice into this tobacco growing country as one of the most beneficial results ever brought about, by a mutual interchange of thought among farmers of different sections, but for some little difficulties which, as yet, I have not been able exactly to get rid of. In the first place, to stack the corn on the wheat field, and go upon it with teams afterwards, is out of the question, for many reasons; in the second, to haul it to the barn at the time it is cut, as Mr. Gilmer says he does, it seems to me is rather "too much pork for a shilling;" for I do think, except wet bricks, green corn is about the heaviest hauling I ever undertook. But, sir, I do feel exceedingly interested in this matter, and hope to see in your columns the views of farmers, more experienced than myself, in relation to it; for if the points above alluded to are settled satisfactorily, I can only say for myself that I would save twice as much good fodder as I now do, and at least a fortnight of good October weather, and I need not tell wheat and tobacco makers what that is worth.

Very truly, yours,

G. F. H.

Elkora, April 9. 1853.

For the Southern Planter.

Appomattox Depot, Amelia, April 4, 1853.

Mr. Editor,-If the following can be published in the Southern Planter early enough to guard the farming community against probable loss and disappointment, it will be well to insert it:

KETTLEWELL AND GUANO.

Hearing from various quarters that the first named article, which has a mixture of guano in its composition, was equal to or better than the Peruvian guano alone, I procured a ton, to experiment with on wheat, last fall. On a field of fifty acres I sowed forward Purple Straw wheat, applying 300 lbs. Peruvian guano to each

(300 lbs.) of the Kettlewell was sown in such a manner as fairly to exhibit the difference in the vegetation, growth and maturity of the crop. Up to this time, (April 4th,) the prospect and difference in favor of the guanoed part is as two or three to one-the Kettlewell being very little better than unaided land. Gentlemen who are hesitating on the subject are invited to call on me, two and a half miles southwest of Appomattox Depot, on the Danville Rail Road, any time between this and harvest, and make up their own verdict. THOMAS MEAUX.

P. S.—I omitted to state that the entire guanoed surface is as green as a leek, and would generally hide a hare.

THE MERINO SHEEP SPECULATION OF 1815-'17.

The Merino sheep speculation was one of the most extraordinary bubbles that ever was known in America. It had its origin, in the year 1815, soon after the treaty of Ghent; and at a time when thousands of our people were actually under the influence of manufacturing mania. In the summer of that year, a gentleman of Boston imported some half dozen sheep from one of the Southern provinces of Spain, whose fleeces were of the finest texture, as it was said, and such undoubtedly was the fact, though the sheep were so thoroughly and completely embedded in tar and every other offensive article, that it would have been very difficult to prove it. But the very offensive appearance of the sheep seemed to imbue them with a mysterious value, that rendered them doubly attractive. It was said that the introduction of these sheep to the United States would enable our manufactories, then in their infancy, to produce broadcloths and other woollen fabrics of a texture that would compete with England and Europe. Mr. Clay was consulted in reference to the sheep, and he at once decided that they were exactly the animals that were wanted.

The first Merino sheep sold, if I recollect right, for fifty dollars the head. They cost a dollar in Andalusia! The speculation was too profitable to stop here; and before a long period had elapsed a small fleet sailed on a sheep speculation to the Medi-

terranean.

By the end of the year 1816 there pro-

the Union, and they had advanced to twelve hundred dollars the head.

Before the autumn of that year had passed away they sold for fifteen hundred dollars the head; a lusty and good looking buck was worth two thousand!

In New England, in the year 1817, the speculation, in consequence of the surplus importation, began to decline; but it steadily and rapidly advanced throughout the Western country. Kentucky, in consequence of the influence of Mr. Clay's opinions, was especially benefited.

In the month of August, 1817, I saw a Merino buck and ewe sold for eight thousand dollars; and even that was deemed a very small price for the animals. They were purchased by a Mr. Samuel Long, a house-builder and contractor, who fancied he had by the transaction secured an immense fortune.

This Mr. Long was actually rabid with the Merino fever; and, in proof of it, it is only necessary to relate a single anecdote. There resided in Lexington-and not more than a mile distant from Mr. Clay's villa of Ashland—a wealthy gentleman, named Samuel Trotter, who was, in fact, the money-king of Kentucky, and who, to a very great extent, controlled the branch of the Bank of the United States. He had two sheep, a buck and an ewe, and Long was very anxious to possess them.

Long often bantered Trotter for the sheep without success; but one day the latter said to the former, "If you will build me such a house, on a certain lot of land, as I shall describe, you shall have the

Merinos."

"Draw your plans," said Long, "and let me see them." The thing was done, and Long eagerly engaged in the enterprise. He built for Trotter a four story brick house, about fifty feet by seventy, on the middle of an acre of land; finished it in the most approved modern style, and enclosed it with a costly fence, and handed it over to Trotter for the two Merino sheep! The establishment must have cost fifteen thousand dollars.

Months before the establishment was completed the price of Merinos declined gradually, and six months had not passed away before they would not command

twenty dollars!

Mr. Long held on to them till they had reached the par value of any other sheep, when he killed them, made a barbecue, called all his friends to the feast, and whilst bably were one thousand Merino sheep in the "goblet went its giddy rounds," like he was not worth a ducat! He was ruined, and soon after died of a broken heart.—New England Farmer.

All communications for the columns of this paper, and all letters of inquiry, to insure prompt attention, must be addressed to Frank:

G. Ruffin, Shadwell, Albemarle County, Va.
All business letters connected with the Planter must be addressed to P. D. Bernard, Richmond, Virginia.

It is indispensably necessary that subscribers ordering a change, should say from what, to what post office they wish the alteration made. It will save time to us and lose none to them.

TO CORRESPONDENTS.

We have a good many articles on hand which are crowded out by want of room or prior communications.

the ruined Venetian, he thanked God that REVIEW OF THE ESSAY ON CALCA-REOUS MANURES.

We make no apology for the length of this able paper. To us, as to many of our readers, no doubt, it is the more acceptable on that account. Subjects of such interest as it treats of cannot be compressed into very small limits without injustice to the public. We cannot better gain a fair hearing for it than by stating that it is the production of the Hon. Willoughby Newton of Linden, in the county of Westmoreland, of whom it may truly be said not only that he is a very worthy gentleman and a true, though retired patriot, but what is, perhaps, more to the purpose in hand, that

"A better farmer ne'er brushed dew from the lawn."

Thoroughly practical, he has in his production, as on previous occasions, given evidence that a knowledge of books and theories is not at all inconsistent with the highest skill in husbandry.

VIRGINIA STATE AGRICULTURAL SOCIETY.

We respectfully invite the particular attention of our readers to the schedule of premiums proposed to be awarded by the Society at its first annual exhibition. We hope there will not be wanting among the farmers, manufacturers and mechanics of Virginia the spirit of generous rivalry and active competition which is essential to the successful attainment of the ends proposed by the Society in offering their premiums upon a scale so liberal and comprehensive. For it is by such means they seek to promote the development of our agricultural resources-to cherish and diffuse the spirit of improvement in all the departments of rural labor and household economy-to foster enterprise and skill in procuring and rearing the best breeds of live-stock-to encourage useful inventions adapted to facilitate and economise the labor of agriculture-and though last, not least, to secure an annual convocation of the friends of improvement from every section of the Commonwealth, by which the contact of the members in kindly social intercourse and public and private discussions with each other may elicit important truthscorrect prevailing errors in opinion and practice, and above all, cement in bonds of enduring friendship and confidential brotherhood those who have hitherto been sadly deficient in l'esprit du corps which ought to signalize them as a class, and whose common interest should incite them to hearty cooperation in securing to themselves the manifold benefits of associated action. The rules and regulations to be observed in conducting the exhibition, with such other matters as may be deemed pertinent by the Executive Committee, will appear in the June number of the Southern Planter.

TIDE WATER AGRICULTURAL SOCIETY

We have received the proceedings of the above Society, which met at Port Royal in the county of Caroline, on the 2d of April, and organized by the election of officers and the adoption of a Constitution and By-Laws. The former President, Dr. E. P. White of Caroline, resigned and was succeeded by Col. Ed. T. Tayloe of King George, President, and James P. Corbin, William P. Taylor, Richard Baylor and Rich'd Royston as Vice Presidents; Rich. H. Garrett, Recording Secretary; John Taylor, Jr. Corresponding Secretary; and R. S. Catlett, Treasurer.

The retiring President delivered a short address, touching upon the benefits of Agricultural Societies, the advantages of the peculiar region, Spottsylvania, Caroline, Essex and the Northern Neck, in agricultural point of view, and the necessity of the farmers of that region keeping up with the spirit of the age in agricultural improvement.

The Fredericksburg Herald says, "To the untiring energy of Dr. E. P. White of Caroline, is Tide Water Virginia chiefly indebted for the agricultural organization now in existence. With an inflexible will which knew no surrender, the Doctor worked on in this labor of unrequited reward until a Society was formed, which has quite recently been placed upon a firm footing." And we have heard from others that mainly, if not entirely, to his exertions do the people of his district owe the existence of this Society.

He is succeeded by a gentleman of known skill, zeal and public spirit; and seconded, as we hope he may be, by his colleagues of the Executive Committee and others, we must anticipate success to the Tide Water Agricultural Society.

VIRGINIA STATE AGRICULTURAL SOCIETY.

The Executive Committee met at the Exchange Hotel on Thursday evening, the 21st of April, 1853. Present P. St. Geo. Cocke, President; Harvie, Overton, F. G. Ruffin, Irby, Peyton and Williams.

Mr. Irby, from the Committee to revise and enlarge the scheme of Premiums for the first Agricultural Fair, made a report, which was laid upon the table for the purpose of conferring with the Committee of the Common Council of the city of Richmond.

Messrs. M'Cance, Anderson and Haskins, the committee above referred to, were then introduced and announced to the Executive Committee the liberal propositions they had unanimously concurred in as fit to be recommended to the Common Hall for its adoption in respect to the furnishing grounds, fixtures and certain accommodations for the first Fair, if the Committee should decide to hold it in Richmond.

Mr. Harvie, from the Committee appointed to confer with rail road and other transportation companies, reported that the Directors of the Danville Rail Road Company had agreed to transport live-stock and other articles designed for the Society's exhibition to and from the place thereof, to the extent their road might be available for that purpose, free of expense for trans-

portation, and that the members of the So-4th. Action or non-action of gypsum, ciety might in like manner pass free. below the falls of the tide-water rivers, Mr. Irby made a similar report respectand on soils respectively originally rich and originally poor; and on the latter, after as well as before their being ing the action of the Directors of the Southside Rail Road Company, so far as that Road might be used in facilitating the made calcareous, 5th. Virginia, or of the accompanying beds of mixture of potash and plaster; or about other earths supposed to contain manuring one hundred and sixty pounds; and sho-

ingredients.

In deciding upon the relative superiority of claims of competitors for this premium, regard will be had to the number of analyses, the diversity and importance of the particular subjects, the accuracy of the methods used and described, the proper direction of investigation, and especially the probable utility and benefit of the results, in their application to agricultural practice and improvement of soils. It is understood that the award of this premium shall not invalidate or lessen any claim which the receiver might otherwise properly present upon some of the same grounds for any other premium offered by the Society on subjects of scientific investigation, useful discovery, or of communications or essays thereupon.

From the Richmond Enquirer.

ACTION OF GUANO ON TOBACCO.

A subscriber furnishes as with the following interesting letter, relative to the importance of guano in raising heavy crops of tobacco. The letter, at this season, particularly, cannot be otherwise than interesting to all growers of tobacco.

Cumberland, Feb. 8, 1853.

My Dear Sir,—Yours, of the 10th ult, did not reach me until last Saturday, in consequence of having been directed to Farmville, instead of Stony Point Mills; and I take the earliest opportunity to reply to it.

My experiment in growing such a heavy crop of tobacco last year, has attracted a great deal of attention, and I take pleasure in detailing it for the benefit of the planting interest of the State. The ground was pretty liberally dressed with home made manures, from my stables, farm-pens and pits, as I think ought always to be done, if we would grow tobacco profitably. When I was going to bed the land for hilling, or rubbing down, which I prefer, I sowed on each acre the following mixture: 2 bushels sifted Peruvian guano, weighing, I judge, about one hundred pounds, intimately mixed with one bushel ground alum salt. I then mixed 21 bushels Mexican guano, weighing, I suppose, one hundred and sixty or one hundred and seventy pounds, and 11 bushels of Kettlewell's mixture of potash and plaster; or about one hundred and sixty pounds; and shovelled them all well together, and sowed the mixture broadcast. The cost of the whole was about \$6 25 per acre. The crop that was planted in good time—I was scarce of plants, and the seasons very difficult—I am sure, gave me two thousand pounds per acre. The tobacco was topped from eighteen to twenty-five leaves, ripened remarkably well to the top leaf, without firing. The tobacco was cultivated for the manufacturers, and is of very fine

quality, and remarkably sweet.

My reasons for this mode of cultivation are few and simple. Our old lands in this region, and, I doubt not generally in middle Virginia, are more deficient in phosphates and potash than any other of the mineral manures; and the tobacco plant must have these elements in order to ripen it well. The Peruvian guano has but a small part of its value in phosphates—only about one-sixth, and five-sixths of its money value, or near forty dollars to the ton, in ammonia, which powerfully stimulates the growth of tobacco, without causing it to ripen, or without giving it the healthy growth which will secure it against firing. The Mexican guano is the richest that has been brought to the country in phosphates, containing 57 to 60 per cent. of ammonia; consequently about five-sixths of its money value is in the phosphates, and about onesixth in ammonia. This suggested the idea of mixing the two. The salt was put with the Peruvian to fix the ammonia, and to furnish the muriates and the soda. But the tobacco plant specially needs potash, especially in its ripening process, the outer coat of the stalk and the stems being formed principally of silicate of potash. Thus, you see, at a glance, what I aimed to accomplish by my mixture.

The success was beyond my expectations. It was the heaviest crop of tobacco I ever saw, and so said every one who

saw it.

The Mexican guano can be had at Baltimore at \$25 per ton, of 2240 lbs. Sterling & Ahrens deal in it. The potash and plaster, Mr. Kettlewell of Baltimore, prepares, and sells at \$2 50 per barrel, of about 320 pounds.

I lost, I may say, no tobacco by fire, while every one of my neighbors had to cut their

crops for fire.

With high regard,
Yours, very truly,
J. S. Armistead.

COLLARS AND BACK BANDS.

Select a good piece of cotton bed-tick, cut strips ten inches wide and of sufficient length—double this strip lengthwise and sew the edges together—turn up and sew the ends loop fashion for the traces to run through, and the back band is finished.

Rip up an old leathern collar, wet it and beat the leather out flat; cut from this a pattern in brown paper, then cut out the bed-tick by the paper pattern—sew up the work with strong double thread; fill the case thus made with clean sound wheat chaff, well packed in with a stick—join the upper ends of the collar by means of a bit of sheep skin, and you have as good a collar as can be bought for \$1 25. Try it.

PAYMENTS TO THE SOUTHERN PLANTER,

From 15th March to 25th April, 1853.

All persons who have made payments early enough to be entered, and whose names do not appear in the following receipt list, are requested to give immediate notice of the omission, in order that the correction may be made in the next issue:

AGENCY.

AM willing to assist gentlemen in purchas-ing and selling farms, stock, and poultry of every description; to attend to receiving and properly forwarding animals; also, to procure suitable overseers and laboring men for farmers and planters: all of which will be attended to for a small commission. My position as Marshal of the Maryland State Agricultural Society gives me advantages of knowing many men, and most good stock, which with my general knowledge of land induces me to extend the agency to land, men and stock. have some fine farms to sell in Talbot county, and several in Baltimore county: subject to my order a number of prize animals, saddle and other stallions, and a few fine mares; Durhams, Devons, Alderney, and Ayrshire; pure long wooled sheep from the best flock in the United States; Chester and Suffolk pigs; Sbanghai and other new and large fowls; also, two fine Jacks. All letters post paid, will reccive prompt attention.

MARTIN GOLDSBOROUGH. Harrisonville, Baltimore Co., Md.

CLASSICAL AND MATHEMATICAL SCHOOL.

RUMFORD ACADEMY, KING WILLIAM, VA.—This school is about two miles from Sharon Church, on the stage road between Richmond and Tappahannock. So healthful is the location, that but few cases of serious sickness have occurred in the school since its establishment in 1804. No expense is spared in providing for the physical comforts of the pupils; treated in every respect as young gentlemen, they are required to conduct themselves as such.

The subscriber, who has been engaged eight years in guiding and instructing youth, will be

aided by competent assistants.

The usual English Course, including Chemistry and Philosophy, an extensive course of Mathematics, and the Latin, Greek and French Languages will be taught. A recess of one week will be given at Easter.

TERMS .- For board and tuition, with every necessary except lights and stationery, from 15th of January to 1st of July, \$84; payable one-half 1st of May, the other half 1st of July. JOHN H. PITTS

ja-tf Aylett's P. O. King William.

SOUTHERN AGRICULTURAL IMPLEMENT MANUFACTORY AND SEED STORE, No. 36 MAIN ST. RICHMOND, Va.

Separator. These Machines have taken the preference wherever introduced, and are recommended—use of easy draught and easily kept in Maryland and Pennsylvania, as the best and most durable and least complicated of any yet introduced—are of easy draught and easily kept in order by the farmer at small cost. This Machine must become the principal, if not the only Machine in use, as it will thresh, clean and bag up at N. U. MOTT, WILLIAM LEWIS and AUGUSTINE CRUMP have entered into coparinership for the purpose of manufacturing all kinds of the most approved Agricultural Implements suitable for the South and West, and have purchased of Mr. J. S. Walthall his stock, and taken his old stand, where they will be happy to serve the pations of the old concern and the public in general, and take this method of calling the attention of all interested in tilling the soil to their extensive stock of superior agricultural implements. They will manufacture and keep for sale Plonghs and Plough Castings of all kinds and of the best materials; also Mott's Horse-Powers and Threshing Machines, with or without Cleaner and Separator. These Machines have taken the preference, wherever introduced, and are recommended by some of the best farmers in Virginia,

one operation-being simple in construction, economical to the farmer, and will thresh more in a given length of time than any Machine in use. This Machine took the premium over some five or six machines at the Maryland State Fair, in October, 1852, by acclamation. We manufacture them from 2 horse-power up to 12 horse-power. We also manufacture Ploughs, Cultivators, Harrows, Grain Cradles, Wheat Drills, Corn and Cob Crushers, Corn Shellers, Straw Cutters of different kinds, among which are Smith's Virginia Patent, being cheap and simple in its construction, Revolving Horse Rakes, Premium Wheat Fans. We will also keep for sale Reapers, Mowing Machines, and all kinds of useful implements, such as are used by Farmers, Planters and Gardeners. We would call par-ticular attention to the Wiley or Mott Premium Double Pointed Cap Plough, of composition metal. One of these Ploughs will last as long as three or four of any other kind now in use, and the metal will stand rocky or stumpy land as well as steel wrought sharesthe shares only costing from 25 to 45 cents each—will plough from 20 to 30 acres each the cap fitting right in the wear of the mouldboard, the cap costing only from 25 to 45 cents. This Plough can be kept in order by the farmer or any of the hands, from five to six years. With this Plough the farmer is his own blacksmith. The Ploughs all warranted, and also warranted to put the ground in better order than any Plongh now in use. Also Wrought Share Ploughs, both Right and Lest; among which are the Improved M'Cormick's, with Cast Landside and Heels; Livingston County Plongh, of all sizes; Subsoil Ploughs of the best patterns.

N. U. Morr being a practical and an experienced workman for fifteen years in the different branches of the business of manufacturing of implements, we feel safe in saying that articles purchased of us will prove of superior workmanship. Call and examine for yourselves, when we will be happy to ex-

hibit our goods.

NEW PLASTER AND BONE MILL.

THE subscriber offers for sale fine Ground and Calcined Plaster, both of the best and purest quality; he has also a Bone Mill attached, and intends to keep a supply of Ground Bones, fine and pure. Farmers and others are invited to call and examine for themselves. His prices shall be as low as the same quality articles can be bought for, North or South. The highest cash price will be paid for dry bones, delivered at his Mill adjoining the Paper Mill.

* If peat cannot be obtained, use garden mould, or clean virgin soil instead.

DIRECTIONS FOR MIXING.—Mix Nos. 1, 2, 3, together—mix Nos. 5, 6, 7, 8, 9, 10, in four or five pails of water, or enough to dissolve the ingredients. When dissolved, add the liquid to the mixture, (1, 2, 3,) and mix as in making mortar. When thoroughly mixed, add No. 4, (the calcined plaster,) which will absorb the liquid and bring the whole to a dry state. Mix under cover in a dry place—pack so as to exclude air—observe the proportions in making small or large quantities. The above receipt will make one ton, which will manure seven and a half acres of land.

Having furnished the above to a number of farmers who have tested its qualities—many thinking it equal to natural guano—the subscribers have nade arrangements to furnish any quantity during this season, and will sell the ingredients exclusive of the Peat, Wood Ashes, Plaster and Salt, (articles on every farm.) at the low price of \$10 per ton. One sugar hogshead will hold ingredients enough for five tons. All orders will be carefully and promptly executed, and sent to any part of the

State.

AGRICULTURAL WAREHOUSE.

HE subscriber continues to manufacture Agricultural Machines, viz. Horse Powers, Threshers, Fan Mills, Hay Rakes, Hunt's Patent Wheat Drill, Hay Presses, Straw Cut-ters, Corn Shellers, Hill Side and Subsoil Ploughs, Corn and Cob Crushers, Cultivators, Harrows, &c.—all of which will be made in the best manner and on the most approved patterns. My Horse Power and Thresher with self-oiling box have been tested three seasons, and uniformly pronounced the best in use. Machines repaired, Castings in Iron and Brass furnished at short notice.
H. BALDWIN,

148 Main street, Richmond.

EAGLE FOUNDERY.

THE subscriber having removed to the large Foundery, just erected by him and fitted out with machinery of the latest and most approved style, is, in addition to the manufacture of Tobacco Flattening Mills, prepared to receive orders for Stationary Steam Engines, Saw and Grist Mills, Agricultural Machines, Tobacco Presses of every description, and all kinds of Iron and Brass Castings. He pledges himself to execute faithfully, and with dispatch, all work entrusted to him, and respectfully solicits a call from his friends and the public generally.

The highest cash prices paid for old cast iron, brass and copper.
